## Monte Carlo Simulation Overview

Jack \& Jill Flash

Traditional financial planning models use rate of return assumptions that do not vary with time. These assumptions often reflect average historical rates of return earned by particular asset classes or combinations thereof over an extended period. Returns have historically fluctuated from year to year in an unpredictable fashion, and future rates of return cannot be guaranteed or even predicted with certainty.

Since rates of return are inherently uncertain, utilizing unvarying return assumptions in a financial model would imply a level of certainty with respect to achieving certain outcomes that does not exist. Nevertheless, this is the basic approach used by traditional financial planning models: to project cash flows and investment capital under a defined set of conditions, where the value of all variables (including the assumed annual rate of return) is set and unchanging so that a single outcome is achieved at the end of the projection period (e.g., life expectancy). This type of projection is usually called "deterministic." A different type of projection, called "stochastic," produces a range of results, rather than a single result, by varying one or more of the dependent variables in the equation. One type of stochastic projection is Monte Carlo simulation (MCS).

MCS projects cash flows and investment capital multiple times-each under a different set of conditions-to yield a range of possible outcomes. Monte Carlo analysis is, therefore, able to incorporate uncertainty into the planning process by demonstrating how different assumptions about the future can impact the likelihood of your meeting or exceeding clearly defined financial planning goals. It is then up to you and your advisor to evaluate the reasonableness of these assumptions, and to modify your proposed financial plan accordingly.

The report that follows illustrates a type of MCS that relies on variable rates of return, which fluctuate from year to year in a random fashion.* The software tool used to produce this Monte Carlo analysis applies these variable rates to selected assets (or combinations thereof) over time, and records the total investment capital at the end of the defined projection period for each iteration or trial. The results of the individual trials are then analyzed, summarized and plotted graphically. A trial whose ending investment capital equals or exceeds your target is considered a success. Conversely, a trial whose ending investment capital falls below your target is considered unsuccessful. A success rate can then be computed simply as the number of successful trials divided by the total number of trials.

Note that the results of any individual trial may not be significant. However, by evaluating the results of all trials together against benchmarks you set, you and your advisor may gain valuable insights into the merits of your proposed financial plan. For instance, if a series of MCS trials yields a success rate that is less than acceptable (e.g., a success rate of only $60 \%$ where you consider a minimum success rate of $80 \%$ to be acceptable), you might consider adopting a different asset allocation design, reducing your post-retirement cash flow needs or delaying your retirement to name just a few examples.

IMPORTANT: The projections or other information generated by this financial plan regarding the likelihood of various investment outcomes are hypothetical in nature, do not reflect actual investment results and are not guarantees of future results. Results herein may vary with each use of the software tool used to generate the MCS analysis that follows and over time.

* Despite the randomness of the return rate series, its basic character is determined by the average rate expected to be earned in the future over an extended period along with an expected range of deviations (i.e., standard deviation) from that average in a given year. In a normally distributed series (i.e., a bell-shaped curve), returns that deviate from the average by one standard deviation are expected to occur approximately $67 \%$ of the time, while returns that deviate from the average by two standard deviations are expected to occur approximately $95 \%$ of the time. This means that variable return series with larger standard deviations will normally produce greater year-over-year fluctuations in projected cash flows and investment capital than series with smaller standard deviations.

## Monte Carlo Simulation Summary

Jack \& Jill Flash
Ending Inflation-Adjusted Investment Capital in 2062
Median investment capital: 1,000 trials
Median investment capital net of outstanding loans: 1,000 trials
232,545 3,262

## Analysis of 1,000 Simulations Run Through 2062

Trial termination value of - $\$ 32,618$
Between trial termination value of $-\$ 32,618$ and $\$ 0$
Between target ending value of \$3,262 and median ending value of \$232,545 2
Above median ending value of \$232,545

NOTE: A successful trial is one where projected investment capital equals or exceeds target investment capital.

1,000 Trial Simulation Summary

■ Trial Termination Value of -\$32,618
Between Trial Termination Value of -\$32,618 and \$0
■ Between Target Ending Value of \$3,262 and Median Ending Value of \$232,545

- Above Median Ending Value of $\$ 232,545$

NOTE: The average number of years before investment capital was reduced to the trial termination value was 34.2 .

MCS Retirement Planning Simulations - 8.7\% ROR/10.8\% StdDev Changing to 9.0\% ROR/11.3\% StdDev
Variable Investment Rates Illustration
Jack \& Jill Flash

The chart above shows projected investment capital over the planning horizon using variable investment returns. Each year a return is randomly generated on the basis of the investment portfolio's average return for the portfolio's combined asset classes. A normal distribution model is used and the range of returns is determined by the standard deviations associated with the different asset classes. Each line in the chart represents the probability that investment capital will exceed the amount shown on the graph at the end of each year. Values and results are not guaranteed.
